## Abstract

Radial Basis Function (RBF) networks are well-established machine learning tools used in many practical problems that can be considered as classification or regression problems. A key component of these networks is their radial functions. These networks acquire adaptive capabilities through a two-stage training technique in most cases. In the first stage, the centers and variances for the radial functions are estimated, and in the second stage, through the solution of a linear system, the external weights for the radial functions are adjusted. However, in many cases, this training technique has reduced performance either due to instability in arithmetic operations or due to the trapping in local minima of the training error. In this paper, a three-stage method is proposed to address the above problems. In the first stage, an initial estimate of the intervals for the network parameter values is made, in the second stage, the network parameter values are adjusted within the intervals of the first phase, and finally, in the third stage of the proposed technique, a local optimization method is used for the final adjustment of the network parameters. The proposed method was tested against some machine learning models from the related literature as well as the original RBF training method on a wide series of classification and regression datasets, found in online databases, and a comparison was made in terms of classification or regression error. It should be noted that although the proposed methodology had very good results in the above measurements, it requires significant computational execution time, due to the use of three phases of processing and adaptation of the network parameters.

## 1. Introduction

Many practical problems can be handled by machine learning models. Such problems appear in physics [1,2], astronomy [3,4], chemistry [5,6], medicine [7,8], economics [9,10], image processing [11], time series forecasting [12] etc. Among the most used machine learning tools, one can detect the Radial Basis Function (RBF) network, expressed using the following definition:

$$R(\vec{x}) = \sum_{i=1}^k w_i \phi(\|\vec{x} - \vec{c}_i\|) \quad (1)$$

The symbols appeared in this equation are defined as follows:

1. The vector  $\vec{x}$  stands for the input pattern. The dimension of each pattern is denoted by  $d$ .

2. The constant  $k$  denotes number of processing units (weights) of the network. The vector  $\vec{w}$  denotes these weights.
3. The vectors  $\vec{c}_i$ ,  $i = 1, \dots, k$  denote the centers of the network.
4. The function  $\phi(x)$  usually represents a Gaussian function with the following definition:

$$\phi(x) = \exp\left(-\frac{(x-c)^2}{\sigma^2}\right) \quad (2)$$

An example plot of this function with  $c = 0$ ,  $\sigma = 1$  is depicted in Figure 1.

**Figure 1.** An example plot for the Gaussian function with  $\sigma = 1$  and  $c = 0$ .

From the graph above, one can conclude that the value of the function rapidly approaches zero as the value of the variable  $x$  moves away from the center  $c$ . The training error of any given  $R(x)$  RBF network is defined as:

$$E(R(\vec{x})) = \sum_{i=1}^M (R(\vec{x}_i) - y_i)^2 \quad (3)$$

The set  $(\vec{x}_i, y_i)$ ,  $i = 1, \dots, M$  denotes the training set of the objective problem and the values  $y_i$  are considered as the actual output for each pattern  $\vec{x}_i$ .

These machine learning models have been incorporated into various practical problems, such as face recognition [13], solutions of differential equations [14,15], stock prediction [16], robotics [17,18], network security [19,20], classification of process faults [21], time series prediction [22], estimation of wind power production [23] etc. Moreover, Park et al. [25] proved that an RBF network with one processing layer is capable of approximating any provided function.

In this paper, the use of a three-stage technique is suggested for the effective training of RBF networks. In the first stage of the technique, the range of values for the parameters of the RBF network is detected. This detection is implemented using the K-Means algorithm [24] for the weights and the variances of the radial functions. After applying the above procedure, a range of values for the network parameters is created which directly depends on the values produced by K-means algorithm. During the second stage of the proposed work, a global optimization procedure is incorporated to optimize the parameters of the RBF network with respect to the equation 3. The training of the parameters is performed inside the interval of values created during the first stage of the technique. In the current work,

the Genetic Algorithm is used as the method of the second phase, but any optimization technique can be incorporated. Finally, in the third stage of the proposed work, a local optimization procedure is applied to the best solution located in the second phase. The purpose of the present technique is first to identify a reliable range of values for the parameters of RBF networks and then to train the network parameters within this range of values, avoiding possible arithmetic instability problems presented by the established method of training RBF networks.

The proposed technique is the application of three distinct procedures in series, where in each stage the results of the previous phase are used. In the first phase, an initial estimate of the centers and variances is made using the K-Means technique. This method is preferred because it is extremely fast to execute and can provide an overview of the search space for neural networks. It is preferred over using random values as this would require a significantly large number of iterations for proper initialization of the parameters. After executing the K-Means technique, a range of values for the network parameters is created with values that are multiples of those produced by the K-Means technique. In this way, on the one hand, the use of the K-Means technique is utilized and, on the other hand, the second-phase optimization algorithm is given the opportunity to search for parameter values that yield lower values of the error function close to the initial values of the first phase. A genetic algorithm is used as the optimization algorithm in the second phase due to its adaptability to any environment and their widespread use in many computational problems. However, any universal optimization technique could be utilized in this phase. However, although genetic algorithms are extremely effective methods of global optimization, they often do not locate exactly a true minimum of the objective function and therefore the help of a local minimization method is deemed necessary. This occurs in the third phase, where a local minimization method is applied to the chromosome with the smallest value produced in the second phase. The minimum found in this phase is also the final result of the algorithm, which is also a configuration of the parameters of the RBF network.

The main characteristics of the present technique are that it uses different techniques in series in order to identify the optimal set of parameters for the machine learning model and to avoid possible overfitting problems. In the first discrete phase, a well-established clustering technique such as the K-Means technique is used to identify an initial range of values for the model parameters. In the second stage, a global optimization algorithm is used to minimize the error function considering the range of values of the first phase and in the last phase a local minimization method will be used to find a guaranteed local minimum of the error function. The method of the last phase guarantees the training of the parameters within the range of values of the first phase.

The remaining of this article has the following organization: in section 2 the suggested method and the accompanied genetic algorithm are introduced, in section 3 the datasets used in the experiments as well the experimental results are shown and discussed and finally in section 4 some conclusions are presented.

## 2. Materials and Methods

The three distinct phases of the proposed method are presented in detail in this section. The discussion initiates with the first phase, where the construction of the ranges for the parameter values is performed using the K-means algorithm. Subsequently, the steps of the used Genetic Algorithm are presented in detail and finally, this section concludes with the description of the final phase, where a local optimization method is applied to the best located chromosome of the second phase. Also, a detailed description of the used datasets is provided in this section.

### 2.1. Related work

A number of techniques have been proposed in recent years for the efficient training of neural networks and the efficient adaptation of parameters. Among them, one can find methods that handle the initialization of the parameters of RBF networks [26–28]. Moreover, Benoudjit et al. provided a discussion on the estimation of kernel widths in these models [29]. Additionally, a series of pruning techniques [30–32] have been introduced aiming to reduce the required number of parameters for networks, providing a solution to the overfitting problem. Also, methods that construct the architecture of RBF networks have been proposed in the recent literature, such as the work of Du et al. [33] or the work of Yu et al. who suggested an incremental design framework for RBF networks [34]. Also, a series of optimization techniques have been used in the past for the minimization of equation 3, such as genetic algorithms [35,36], the Particle Swarm Optimization method [37,38], the Differential Evolution technique [39] etc. Furthermore, the rapid increase in the use of parallel computing techniques in recent decades has resulted in the publication of a series of relevant scientific papers that exploit these techniques [40,41]. Recently, Rani et al. proposed an improved PSO optimizer that integrates a differential search mechanism for efficient RBF network training [42]. Moreover, Karamichailidou et al. suggested a novel method for RBF training using variable projection and fuzzy means [43].

### 2.2. The first phase of the proposed method

The method of K-means, used widely in machine learning, is incorporated in the first phase for the location of the ranges for the centers and variances of the model. This method is incorporated to locate the centers and the variances of the possible groups of a series of points. Furthermore, a series of extensions of this method have been published during the past years, such as the Genetic K-means algorithm [44], the unsupervised K-means algorithm [45], the Fixed-centered K-means algorithm [46] etc. A detailed review of the K-means method can be located in the work of Oti et al. [47]. The K-means method is presented in Algorithm 1. A graphical representation is provided in Figure 2.

**Algorithm 1** The main steps of the K-means algorithm.

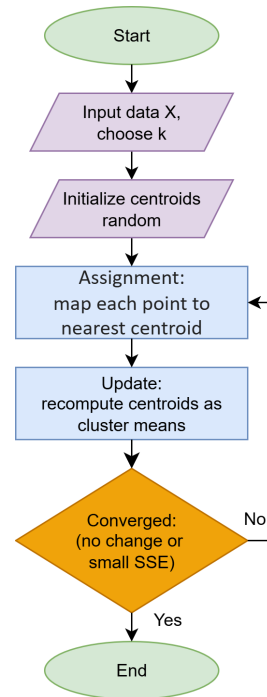

1. **Input:** The set of patterns of the objective problem  $(\vec{x}_i), i = 1, \dots, M$
2. **Input:** the number of centers  $k$ .
3. **Output:** The vectors  $\vec{c}_i, i = 1, \dots, k$  and the quantities  $\sigma_i, i = 1, \dots, k$
4. **Set**  $S_j = \{\}, j = 1..k$ , as the sets of samples belonging to the same group.
5. **For** each pattern  $x_i, i = 1, \dots, M$  **do**
  - (a) **Set**  $j^* = \min_{i=1}^k \{D(x_i, c_j)\}$ .
  - (b) **Set**  $S_{j^*} = S_{j^*} \cup \{x_i\}$ .
6. **EndFor**
7. **For** each center  $c_j, j = 1..k$  **do**
  - (a) **Calculate** as  $M_j$  the number of points belonging to the group  $S_j$
  - (b) **Compute**  $c_j$  as

$$c_j = \frac{1}{M_j} \sum_{i=1}^{M_j} x_i$$

8. **EndFor**
9. **Calculate** the quantities  $s_j$  as

$$\sigma_j^2 = \frac{\sum_{i=1}^{M_j} (x_i - c_j)^2}{M_j}$$

10. **Terminate** the algorithm when there is no further changes in centers  $c_j$ .
11. **Go to** step 5.

**Figure 2.** A graphical presentation of the K-means algorithm.

After the calculation of  $\vec{c}_i, i = 1, \dots, k$  and the quantities  $\sigma_i, i = 1, \dots, k$ , the method locates the bound vectors  $\vec{L}, \vec{R}$  for the parameters of the RBF network. The dimension of the bound vectors is defined as:

$$n = (d + 2) \times k \quad (4)$$

For the calculation of the bound vectors the procedure presented in Algorithm 2 is utilized.

---

**Algorithm 2** Algorithm used to obtain the bound vectors  $\vec{L}, \vec{R}$ 

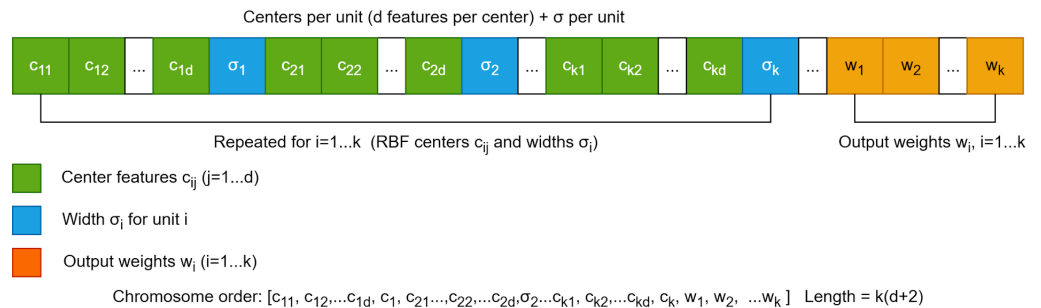

---

1. **Input:** The vectors  $\vec{c}_i, i = 1, \dots, k$  and the quantities  $\sigma_i, i = 1, \dots, k$  of the K-means procedure.
  2. **Input:** the initial bound for the weight vector  $\vec{w}$ , denoted as  $B_w > 0$ .
  3. **Input:** the scaling factor  $F \geq 1$ .
  4. **Output:** the vectors  $\vec{L}, \vec{R}$ .
  5. **Set**  $m = 0$
  6. **For**  $i = 1..k$  **do**
    - (a) **For**  $j = 1..d$  **do**
      - i. **Set**  $L_m = -F \times c_{ij}, R_m = F \times c_{ij}$
      - ii. **Set**  $m = m + 1$
    - (b) **EndFor**
    - (c) **Set**  $L_m = -F \times \sigma_i, R_m = F \times \sigma_i$
    - (d) **Set**  $m = m + 1$
  7. **EndFor**
  8. **For**  $j = 1, \dots, k$  **do**
    - (a) **Set**  $L_m = -B_w, R_m = B_w$
    - (b) **Set**  $m = m + 1$
  9. **EndFor**
- 

### 2.3. The second phase of the proposed method

During the second phase, an optimization procedure is utilized to minimize the equation 3 inside the bound vectors  $\vec{L}, \vec{R}$  of the first phase. In the proposed implementation, the Genetic Algorithm was incorporated during the second phase. Genetic algorithms are evolutionary methods that are based on randomly produced solutions of the objective problem. The trial solutions of the genetic algorithm are commonly called chromosomes, and they are evolved through some operations that mimic some natural processes, such as selection, crossover and mutation. Genetic algorithms have been used in a wide series of problems, such as energy problems [48], water distribution [49], problems appearing in banking transactions [50], optimization of neural networks [51] etc. Also, another advantage of Genetic Algorithms is that they can easily adopt parallel programming techniques in order to speed up the evolutionary process [52,53]. The layout of the chromosomes used in the obtained genetic algorithm is presented in Figure 3. In this layout the following assumptions hold:

1. The value  $c_{ij}$  denotes the  $j$  element of the  $i$  center of the RBF network, with  $i \in [1, k]$  and  $j \in [1, d]$ .
2. The value  $\sigma_i$  represents the  $\sigma$  parameter for the corresponding radial function.
3. The value  $w_i, i \in [1, k]$  represents the weight for the corresponding radial function.

**Figure 3.** The layout of chromosomes used in the second stage of the proposed method.

The steps of algorithm used in the second phase are the following:

1. **Initialization step.**

- (a) **Set** the parameters of the genetic algorithm:  $N_c$  the number of chromosomes,  $N_g$  as the maximum number of allowed generations,  $p_s$  the selection rate and  $p_m$  the mutation rate.
- (b) **Initialize** every chromosome  $g_i$ ,  $i = 1, \dots, N_c$  of the population as vector of double numbers. The layout of each chromosome follows the scheme of Figure 3 and the initialization is performed inside the bound vectors  $\vec{L}$ ,  $\vec{R}$ .
- (c) **Set**  $k = 0$ . This variable denotes the number of generations.

2. **Fitness calculation step.**

- (a) **For**  $i = 1, \dots, N_c$  **do**
  - i. **Produce** an RBF network  $R_i = R(\vec{x}, \vec{g}_i)$  using the parameters encoded in the chromosome  $\vec{g}_i$ .
  - ii. **Estimate** the related fitness value  $f_i$  as

$$f_i = \sum_{j=1}^M (R(\vec{x}_j, \vec{g}_i) - y_j)^2 \quad (5)$$

- (b) **End For**

3. **Genetic operations step.**

- (a) Selection procedure: During this procedure the chromosomes are sorted according to their fitness values. The first  $p_s \times N_c$  of them are transferred without any change to the next generation. The remaining chromosomes will be substituted by offsprings produced using the operations of crossover and mutation.
- (b) Crossover procedure: During this procedure In this procedure  $(1 - p_s) \times N_c$  new chromosomes will be constructed. For each pair  $(\tilde{z}, \tilde{w})$  of new chromosomes, two chromosomes  $(z, w)$  are chosen using the procedure of tournament selection. The new offsprings are produced following the scheme:

$$\begin{aligned} \tilde{z}_i &= a_i z_i + (1 - a_i) w_i \\ \tilde{w}_i &= a_i w_i + (1 - a_i) z_i \end{aligned} \quad (6)$$

Where the numbers  $a_i$  are random numbers having the property  $a_i \in [-0.5, 1.5]$  [54].

- (c) Mutation procedure: Select a random number  $r \in [0, 1]$  for each element  $t_j, j = 1, \dots, n$  of every chromosome  $g_i$ . If  $r \leq p_m$ , then this element is altered according to the following scheme:

$$t'_j = \begin{cases} t_j + \Delta(k, R_j - t_j), & t = 0 \\ t_j - \Delta(k, t_j - L_j), & t = 1 \end{cases} \quad (7)$$

The value  $t$  is a random number that can be either 0 or 1. The function  $\Delta(k, y)$  is provided by the following equation:

$$\Delta(k, y) = y \left( 1 - r^{\left( 1 - \frac{k}{N_g} \right)} \right) \quad (8)$$

4. **Termination check step.**

- (a) **Set**  $k = k + 1$

- (b) **If**  $k < N_g$  then go to Fitness Calculation Step 188
- (c) **Else return** the best located chromosome  $g^*$  as the outcome of this algorithm. 189

#### 2.4. The final phase of the proposed method 190

In the final phase of the proposed method, a local optimization procedure is applied 191  
to the outcome of the previous phase, in order to locate an actual minimum for the training 192  
error of the RBF network. In this work, a BFGS variant of Powell [55] was utilized as the 193  
local search procedure. This variant can preserve the bounds of the objective function in an 194  
efficient way. During the past years, a series of modifications to the BFGS method have 195  
been introduced, such as the limited memory variant L-BFGS ideal for large scale problems 196  
[56] or the Regularized Stochastic BFGS Algorithm [57]. Also, Dai published an article on 197  
the convergence properties of the BFGS method [58]. The main steps of the final phase of 198  
the algorithm are: 199

1. **Get** the best chromosome  $\vec{g}^*$  of the previous phase. 200
2. **Produce** the corresponding RBF network  $R^* = R(\vec{x}, \vec{g}^*)$ . 201
3. **Minimize** the training error of the network  $R^*$  using the local search procedure of 202  
this phase. 203
4. **Apply** the final model to the test set and obtain the corresponding test error. 204

A summary flow chart showing the sequence of the various phases of the proposed work is 205  
presented in Figure 4. 206

**Figure 4.** Summary flowchart of the proposed method.

### 2.5. The experimental datasets.

The proposed method was tested on a wide series of classification and regression problems, that can be downloaded UCI database [59], the KEEL database [60] and the STATLIB database [61]. The following classification datasets were used in the experiments:

1. **Appendictis**, which is used for medical purposes [62].
2. **Alcohol**, a dataset related to alcohol consumption [63].
3. **Australian**, a dataset related to economics [64].
4. **Balance** dataset [65], that contains measurements from various psychological experiments.
5. **Cleveland**, a medical dataset which was discussed in a series of papers [66,67].
6. **Circular** dataset, which is an artificial dataset.
7. **Dermatology**, regarding some dermatology problems [68].
8. **Ecoli**, regarding some protein problems [69].
9. **Hayes-roth** dataset [70].
10. **Heart**, a medical dataset used to detect some heart diseases [71].
11. **HeartAttack**, a medical dataset related to the presence of heart diseases [72].
12. **Housevotes**, a dataset that contains data from voting in the Congressional of USA [73].

13. **Ionosphere**, a dataset related to the ionosphere [74,75]. 225
14. **Liverdisorder**, a medical dataset [76,77]. 226
15. **Lymography** [78]. 227
16. **Mammographic**, which is related to the prediction of breast cancer [79]. 228
17. **Parkinsons**, used for the detection of Parkinson's disease [80,81]. 229
18. **Pima**, a medical dataset regarding diabetes[82]. 230
19. **Popfailures**, a dataset that contains data from climate experiments [83]. 231
20. **Regions2**, a medical dataset related to the detection of liver problems [84]. 232
21. **Saheart**, a medical dataset related to the detection of heart diseases[85]. 233
22. **Segment** dataset [86]. 234
23. **Statheart**, a medical dataset related to the presence of heart diseases. 235
24. **Spiral**, an artificial dataset with two classes. 236
25. **Student**, a dataset that contains data from experiments in schools [87]. 237
26. **Transfusion** [88]. 238
27. **Wdbc**, regarding the detection of breast cancer [89,90]. 239
28. **Wine**, a dataset regarding measurements about wines [91,92]. 240
29. **EEG**, which is contains some EEG recordings [93,94]. The following cases were used 241  
from this dataset: Z\_F\_S, ZO\_NF\_S, ZONF\_S and Z\_O\_N\_F\_S. 242
30. **Zoo**, used for the classification of animals [95] . 243

The number of patterns and classes for each classification dataset are shown in Table 1. 244

**Table 1.** The column DATASET represents the name of the dataset. The column Patterns stands for the number of patterns in the dataset and the column Number of Classes represents the number of distinct classes in the mentioned dataset.

DATASET	Patterns	Number of Classes
ALCOHOL	476	4
APPENDICITIS	106	2
AUSTRALIAN	690	2
BALANCE	625	3
CLEVELAND	297	5
CIRCULAR	500	2
DERMATOLOGY	368	6
ECOLI	336	8
HEARTATTACK	303	2
HAYES ROTH	132	3
HEART	270	2
HOUSEVOTES	232	2
IONOSPHERE	351	2
LIVERDISORDER	345	2
LYMOGRAPHY	148	4
MAMMOGRAPHIC	830	2
PARKINSONS	195	2
PIMA	768	2
POPFAILURES	540	2
SPIRAL	2000	2
REGIONS2	622	5
SAHEART	462	2
SEGMENT	2300	7
STATHEART	270	2
STUDENT	403	2
TRANSFUSION	748	2
WDBC	569	2
WINE	179	3
Z_F_S	300	3
Z_O_N_F_S	500	5
ZO_NF_S	500	3
ZONF_S	500	2
ZOO	101	7

Also, the following regression datasets were used:

1. **Abalone**, a dataset related to the age of abalones [96].
2. **Airfoil**, a dataset provided by NASA [97].
3. **Auto**, a dataset used to calculate the fuel consumption in cars [98].
4. **BK**, used for the prediction of points scored in some basketball games.
5. **BL**, a dataset that includes data from various electricity experiments.
6. **Baseball**, used to estimate the income of baseball players.
7. **Concrete**, a dataset used in civil engineering [99].
8. **DEE**, a dataset used for the calculation of the price of electricity.
9. **FA** dataset, related to fat measurements.
10. **Friedman**[100].
11. **FY**, regarding some fruit flies.
12. **HO**, a dataset obtained from the STATLIB repository.
13. **Housing**, used to predict the price of houses [101].
14. **Laser**, a dataset that contains measurements from various physics experiments.
15. **LW**, a dataset regarding the weight of babes.

16. **Mortgage**, an economics dataset.
17. **PL**, a dataset obtained from the STALIB repository.
18. **Plastic**, a dataset regarding some problems in plastics.
19. **Quake**, a dataset regarding the measurements of earthquakes.
20. **SN**, a dataset related to trellising and pruning.
21. **Stock**, which is a dataset regarding stocks.
22. **Treasury**, an economics dataset.

### 3. Results

#### 3.1. Experimental results

All the experiments were executed on a Debian Linux system with 128GB of RAM. The programming language used was C++ and for the optimization method, the OPTIMUS optimization environment [102] available from <https://github.com/itsoulos/GlobalOptimus.git> (accessed on 20 September 2025) was incorporated. The results were validated using the ten - fold cross validation technique. For the classification datasets, the average classification error, calculated on the corresponding test set, is reported. This quantity is expressed using the following equation:

$$E_C(N(\vec{x}, \vec{w})) = 100 \times \frac{\sum_{i=1}^N (\text{class}(N(\vec{x}_i, \vec{w})) - y_i)}{N} \quad (9)$$

Where the set  $T$  denotes the related test set and it is defined as  $T = (x_i, y_i)$ ,  $i = 1, \dots, N$ . Similarly, for the regression datasets, the average regression is reported which is calculated as follows:

$$E_R(N(\vec{x}, \vec{w})) = \frac{\sum_{i=1}^N (N(\vec{x}_i, \vec{w}) - y_i)^2}{N} \quad (10)$$

Table 2 contains the values for each parameter of the proposed method.

**Table 2.** The values for each parameter of the proposed method.

NAME	MEANING	VALUE
$k$	Number of radial functions	10
$F$	Scaling factor	2.0
$B_w$	Bound value for the weights	10.0
$N_c$	Number of chromosomes	500
$N_g$	Maximum number of generations	200
$p_s$	Selection rate	0.1
$p_m$	Mutation rate	0.05

In the experimental tables the following notation is used:

1. The column DATASET denotes the name of the used dataset.
2. The column BFGS represents the incorporation of the BFGS procedure [103] for the training of an artificial neural network [104,105] with 10 weights.
3. The column ADAM denotes the incorporation of the Adam optimization method [106,107] for the training of a neural network with 10 hidden nodes.
4. The column RBF-KMEANS is used to denoted the original training method of RBF networks.
5. The column NEAT (NeuroEvolution of Augmenting Topologies) [108] stands for the method NEAT incorporated in the training of neural networks.
6. The column DNN stands for the incorporation of a deep neural network as implemented in the Tiny Dnn library, that can be downloaded freely from <https://github.com/tiny-dnn/tiny-dnn>.

- [//github.com/tiny-dnn/tiny-dnn](https://github.com/tiny-dnn/tiny-dnn)(accessed on 20 September 2025). The implemented network was trained with the AdaGrad optimizer [109].
7. The column BAYES stands for the usage of the Bayesian optimizer as implemented in the freely available library BayesOpt [110] for the training of a neural network with  $H = 10$  processing nodes. The code can be downloaded from <https://github.com/rmcantin/bayesopt> (accessed on 20 September 2025).
  8. The column GENRBF stands method introduced in [111] for RBF training.
  9. The column PROPOSED represents the results obtained by the current work.
  10. The row average stands for the average regression or classification error for all datasets.
  11. The bold notation is used in all experimental tables to indicate the machine learning method with the lowest classification or regression error.

**Table 3.** Experimental results for the classification datasets with the machine learning methods mentioned in this section.

ZOO	10.70%	14.13%	20.27%	16.20%	14.70%	21.93%	33.50%	<b>9.80%</b>
AVERAGE	<b>33.50%</b>	<b>33.73%</b>	<b>32.77%</b>	<b>25.52%</b>	<b>27.21%</b>	<b>28.54%</b>	<b>34.89%</b>	<b>19.45%</b>

Table 3 compares the performance of eight methods on thirty-three classification datasets. The mean percentage error clearly shows that the proposed method is best overall at 19.45%, followed by DNN at 25.52%, then BAYES 27.21%, RBF-KMEANS 28.54%, NEAT 32.77%, BFGS 33.50%, ADAM 33.73%, and GENRBF 34.89%. Relative to the strongest competitor, DNN, the proposed method lowers the average error by 6.07 points, about 24%. The reduction versus the classical BFGS and ADAM is about 14 points, roughly 42%, and versus RBF-KMEANS about 9.1 points, roughly 32%.

At the level of individual datasets, the proposed method delivers strikingly low errors in several cases. On Spiral, it drops to 13.26% while others are around 45–50%;

on Wine it reaches 9.47% versus 21–60%; on Wdbc it achieves 5.54% versus 7–35%. On Z\_F\_S, ZO\_NF\_S, ZONF\_S, and Cleveland it attains the best or tied-best results. On Heart, HeartAttack, Statheart, Regions2, Saheart, Pima, Australian, Alcohol, and HouseVotes, the results are also highly competitive, usually best or within the top two. There are, however, datasets where other methods prevail: DNN clearly leads on Segment and HouseVotes and is very strong on Dermatology; RBF-KMEANS is best on Appendicitis; and ADAM wins narrowly on Student and Balance. In cases like Balance, Popfailures, Dermatology, and Segment, the proposed method is not the top performer, though it remains competitive.

Overall, the proposed method offers the lowest average error and a consistent advantage across a wide range of problems, with substantial gains over all classical and modern baselines. Despite local exceptions where DNN, ADAM, or RBF-KMEANS come out ahead, the approach appears more generalizable and stable, achieving systematically low errors and large improvements on challenging datasets, which supports its practical use as a default choice for classification.

## Method Comparison

### Pairwise Wilcoxon tests

The Figure 5 and the Table 4 summarizes paired Wilcoxon signed-rank tests comparing the PROPOSED method against each competitor on the same 33 classification datasets. The column  $n$  is the number of paired datasets,  $V$  is the Wilcoxon signed-rank statistic,  $r_{rank,biserial}$  is the rank-biserial effect size (range -1 to 1, with more negative meaning PROPOSED has lower error),  $conf_{low}$  and  $conf_{high}$  give the 95% Hodges-Lehmann confidence interval for the median paired difference (PROPOSED - competitor) in percentage point error,  $p$  is the raw p-value,  $p_{adj}$  is the Holm-adjusted p-value, and  $p_{signif}$  is the significance code. Because all confidence intervals are entirely negative, the PROPOSED method consistently shows lower error than each baseline, not just statistical significance but a stable direction of effect across datasets. Adjusted p-values remain very small in every comparison, from  $4.33 \times 10^{-6}$  (vs GENRBF) up to  $1.31 \times 10^{-4}$  (vs DNN), yielding \*\*\*\* everywhere except the DNN comparison, which is \*\*\*. Effect sizes are uniformly large in magnitude. The strongest difference is against GENRBF with  $r \approx -0.998$  and a 95% CI for the median error reduction of roughly -19.12 to -12.01 percentage points. Very large effects also appear versus NEAT ( $r \approx -0.980$ , CI  $\approx [-18.40, -7.15]$ ) and RBF-KMEANS ( $r \approx -0.977$ , CI  $\approx [-12.11, -4.90]$ ). Comparisons with BFGS ( $r \approx -0.954$ , CI  $\approx [-18.51, -7.96]$ ) and ADAM ( $r \approx -0.943$ , CI  $\approx [-19.42, -8.03]$ ) remain strongly favorable. The smallest, yet still large, effect is against DNN ( $r \approx -0.882$ ) with a clearly negative CI  $\approx [-8.93, -3.09]$ . Taken together, the results show consistent, substantial reductions in classification error for the PROPOSED method across all baselines, with very large effect sizes, tight negative confidence intervals, and significance that survives multiple-comparison correction.

Also, a comparison in terms of precision and recall for the classification datasets, between the original training method for RBF networks and the proposed one is depicted in Table 5.

<b>AVERAGE</b>	<b>28.82</b>	<b>21.39</b>	<b>13.99</b>	<b>11.82</b>	<b>9.18</b>	<b>9.56</b>	<b>13.38</b>	<b>5.87</b>

Table 6 evaluates the performance of eight regression methods on twenty-one datasets using absolute errors. The average error shows a clear overall advantage for the proposed method at 5.87, followed by BAYES at 9.18, RBF-KMEANS at 9.56, DNN at 11.82, NEAT at 13.99, GENRBF at 13.38, ADAM at 21.39, and BFGS at 28.82. Relative to the best competing average, BAYES, the proposed method reduces error by about 3.31 points ( $\approx 36\%$ ). The reduction versus RBF-KMEANS is about 3.69 points ( $\approx 39\%$ ), versus DNN about 5.95 points ( $\approx 50\%$ ), and relative to NEAT and GENRBF the drops are roughly 58% and 56%, respectively. The advantage is even larger against ADAM and BFGS, where the mean error is nearly halved or more.

Across individual datasets, the proposed method attains the best value in roughly two thirds of the cases. It is clearly first on Auto, BL, Concrete, Dee, Housing, FA, HO, Mortgage, PL, Plastic, Quake, Stock, and Treasury, with particularly large margins on Housing and Stock where errors fall to 15.36 and 1.44 while other methods range from tens to hundreds. On Airfoil it is essentially tied with the best at 0.004, while BFGS is slightly lower at 0.003. There are datasets where other methods lead, such as Abalone where ADAM and BAYES are ahead; Friedman and Laser where BFGS gives the best value; BK where DNN and RBF-KMEANS lead; and PY where RBF-KMEANS is lower. Despite these isolated exceptions, the proposed method remains consistently among the top performers and most often the best.

Overall, the proposed approach combines a very low average error with broad superiority across diverse problem types and error scales, from thousandths to very large magnitudes. The consistency of the gains and the size of the margins over all baselines indicate it is the most efficient and generalizable choice among the regression methods considered.

**Figure 6.** Statistical comparison of the obtained results in the regression datasets using a variety of machine learning methods.

The Figure 6 and the Table 7 summarizes paired Wilcoxon signed-rank tests between PROPOSED and each method on the same regression datasets. In every comparison the 95% confidence interval is entirely negative, so PROPOSED consistently attains lower error than each baseline. Holm-adjusted p-values range from about  $5.86 \times 10^{-4}$  to 0.0063, yielding \*\* or \*\*\* across all pairings, indicating strong though not extreme significance. Effect sizes are very large in absolute value, implying a consistent sign of the differences across datasets. The strongest dominance is against NEAT with  $r \approx -1$  and  $V=0$ , meaning that in every non-tied pair PROPOSED was better, with a confidence interval roughly  $[-9.93, -0.16]$ . Similarly large effects appear against GENRBF ( $r \approx -0.976$ , CI  $[-10.25, -0.098]$ ) and RBF-KMEANS ( $r \approx -0.945$ , CI  $[-4.52, -0.034]$ ), the upper bound near zero indicates that the typical improvement can range from very small to several points depending on the dataset. Against BFGS and ADAM the effects remain very large ( $r \approx -0.889$  and  $r \approx -0.857$ , respectively) with wider intervals  $[-20.51, -0.316]$  and  $[-27.34, -0.0416]$ , showing substantial heterogeneity in the magnitude of error reduction while the direction remains in favor of PROPOSED. The most challenging comparison is with DNN: although  $|r|$  is still very large ( $\approx 0.900$ ), the CI is narrow and close to zero  $[-11.09, -0.012]$ , implying that while superiority is consistent, the typical error reduction may be small in many cases.

Overall, the results demonstrate that PROPOSED systematically outperforms all alternatives on regression, with very large rank-based effect sizes, negative and robust confidence intervals, and significance that survives multiple-comparison correction. The strength of the improvement varies by problem and is more modest against DNN, but the direction of the effect is consistently in favor of PROPOSED across all comparisons.

### 3.2. Experiments with different values of scale factor $F$

In order to evaluate the stability and reliability of the proposed method when its critical parameters change, a series of additional experiments were executed. In one of them, the stability of the technique was studied with the change of the scale factor  $F$ . This factor controls the width of the value interval for the network parameters and is a multiple of the initial values estimated by the K-means method of the first phase. In this series of experiments, the value of  $F$  was altered in the range  $[1, 8]$ .

Table 8 presents the effect of the scale factor  $F$  on the performance of the proposed machine learning model. The parameter  $F$  takes four different values, 1, 2, 4, and 8, and for each dataset the classification error rate is reported. Analyzing the mean values, it is observed that  $F = 2$  and  $F = 4$  achieve the best overall performance, with average errors of 19.45% and 18.53% respectively, compared to 20.99% for  $F = 1$  and 18.60% for  $F = 8$ . This indicates that selecting an intermediate value of the initialization factor improves performance, reducing the error by about two percentage points relative to the baseline case of  $F = 1$ . At the individual dataset level, interesting patterns emerge. For example, in Sonar the error drops significantly from 32.90% at  $F = 1$  to 18.75% at  $F = 4$ , suggesting that the parameter  $F$  strongly influences performance in certain problems. In contrast, in Spiral increasing  $F$  worsens the results, as the error rises from 12.03% at  $F = 1$  to 23.56% at  $F = 8$ . Similarly, in the Australian dataset a gradual increase of  $F$  from 1 to 8 systematically improves performance, reducing the error from 24.04% to 20.59%. Overall, the data show that the effect of the scale factor is not uniform across all problems, but the general trend indicates improvement when  $F$  increases from 1 to 2 or 4. Choosing  $F = 4$  appears to yield the best mean result, although the difference compared with  $F = 8$  is very small. Therefore, it can be concluded that tuning this parameter plays an important role in the stability and accuracy of the model, and that intermediate values such as 4 constitute a good general choice.

**Table 8.** Experimental results on the classification datasets where the proposed method was applied and the critical parameter  $F$  was altered from  $F = 1$  to  $F = 8$ .

AVERAGE	<b>20.99%</b>	<b>19.45%</b>	<b>18.53%</b>	<b>18.60%</b>

Table 9 shows the effect of the scale factor  $F$  on the performance of the proposed regression model. Based on the mean errors, the best overall performance occurs at  $F = 4$  with an average error of 5.68, while the values for  $F = 1$ ,  $F = 2$  and  $F = 8$  are 5.94, 5.87, and 5.78, respectively. The differences across the four settings are not large, but they indicate that intermediate values and especially  $F = 4$  tend to offer the best accuracy stability trade-off. At the level of individual datasets, substantial variations are observed. For Friedman the reduction is dramatic, with error dropping from 6.74 at  $F = 1$  to 1.41 at  $F = 8$ , highlighting that proper tuning of  $F$  can have a strong impact on performance. Laser shows a similarly large improvement, from 0.027 at  $F = 1$  to just 0.0024 at  $F = 8$ . Mortgage also improves markedly, from 0.67 at  $F = 1$  to 0.015 at  $F = 8$ . By contrast, in some datasets the value of  $F$  has little practical effect, such as Quake and HO, where errors remain nearly constant regardless of  $F$ . There are also cases like Housing where increasing  $F$  degrades performance, with error rising from 14.64 at  $F = 1$  to 18.48 at  $F = 8$ . Overall, the results indicate that the scale factor  $F$  has a significant but nonuniform influence on model performance. In some datasets it sharply reduces error, while in others its impact is negligible or even negative. Nevertheless, the aggregate picture based on the mean errors

suggests that  $F = 4$  and  $F = 8$  yield the most reliable results, with  $F = 4$  being the preferred choice for a general-purpose setting.

In Figure 7, the significance levels are presented for the comparisons between different values of the parameter  $F$  in the proposed machine learning method based on the classification datasets. The analysis shows that the comparison between  $F = 1$  and  $F = 2$  results in high statistical significance with  $p < 0.01$ , indicating that the transition from the initial value to  $F = 2$  has a substantial impact on performance. Similarly, the comparison between  $F = 2$  and  $F = 4$  also shows high statistical significance with  $p < 0.01$ , suggesting that further increasing the parameter continues to positively affect the results. However, the comparison between  $F = 4$  and  $F = 8$  is characterized as not statistically significant, since  $p > 0.05$ , which means that increasing the parameter beyond  $F = 4$  does not bring a meaningful difference in performance. Overall, the findings indicate that smaller values of  $F$  play a critical role in improving the model, while increases beyond 4 do not lead to further statistically significant improvements.

**Figure 7.** Statistical comparison for the experimental results on the classification datasets using the proposed method and a variety of values for the scale parameter  $F$ .

In Figure 8, the significance levels are presented for the comparisons between different values of the parameter  $F$  in the proposed method based on the regression datasets. The results show that none of the comparisons  $F = 1$  vs  $F = 2$ ,  $F = 2$  vs  $F = 4$ , and  $F = 4$  vs  $F = 8$  exhibit statistically significant differences, since in all cases  $p > 0.05$ . This means that variations in the parameter  $F$  do not substantially affect the performance of the model in regression problems. Therefore, it can be concluded that the choice of the  $F$  value is not of critical importance for these datasets and that the model remains stable regardless of the specific setting of this parameter.

**Figure 8.** Statistical comparison for the experimental results on the regression datasets using the proposed method and a variety of values for the scale parameter  $F$ .

### 3.3. Experiments with differential initialization methods for variances

Additionally, the stability of the proposed method was checked using a different way of calculating the range of values of the  $\sigma$  parameters of the radial functions. In this work, the value of the variance produced by the K-means algorithm was used as an initial estimate of the  $\sigma$  parameters. This calculation scheme is denoted as  $\sigma_1$  in the following experimental tables. In this additional set of experiments, two more techniques were used, which will be denoted as  $\sigma_{\text{avg}}$  and  $\sigma_{\text{max}}$  in the following tables. In the  $\sigma_{\text{avg}}$  the following calculation is performed:

$$\sigma_{\text{avg}} = \frac{1}{k} \sum_{i=1}^k \sigma_i \quad (11)$$

Subsequently  $\sigma_{\text{avg}}$  is used to determine the range of values of the  $\sigma$  parameters of the radial functions of the network. In the  $\sigma_{\text{avg}}$  the following quantity is calculated:

$$\sigma_{\text{max}} = \max \sigma_i \quad (12)$$

Afterwards this quantity is used for the determination of the range of values for the  $\sigma$  parameters of the radial functions.

Table 10 presents the effect of three different calculation techniques for the  $\sigma$  parameters used in the radial basis functions of the RBF model. The techniques are a fixed value  $\sigma_1$ , the mean distance-based initialization ( $\sigma_{\text{avg}}$ ), and the maximum distance-based ini-

tialization ( $\sigma_{\max}$ ). Based on the mean errors, the maximum-distance technique yields the lowest overall error at 19.18%. Very close is the mean-distance technique at 19.27%, while the simple  $\sigma_1$  initialization has a slightly higher error of 19.45%. Although the differences among the three approaches are small, the two adaptive methods ( $\sigma_{\text{avg}}$  and  $\sigma_{\max}$ ) tend to produce marginally better overall performance. At the individual dataset level, behaviors vary. For example, on Wine the  $\sigma_{\max}$  choice reduces error to 7.06%, far below the 9.47% obtained with  $\sigma_1$ . On Dermatology,  $\sigma_1$  performs better than the other two, whereas on Segment the mean-based option is preferable. In some cases the differences are minor e.g., Circular, Pima, and Popfailures where all techniques are comparable; in others the choice of technique materially affects performance, as in Transfusion, where error drops from 26.04% with  $\sigma_1$  to about 22.78% with the other two methods. Overall, the statistical picture indicates that no single technique dominates across all datasets. Nevertheless, methods that adapt  $\sigma$  to the geometry of the data ( $\sigma_{\text{avg}}$  and  $\sigma_{\max}$ ) tend to yield more reliable and stable results, while the fixed value lags slightly. The average differences are modest, but for certain problems the choice can significantly impact final performance.

**Table 10.** Experimental results on the classification datasets, where the proposed method was applied using different mechanisms for the calculation of the quantities  $\sigma$  used in the radial functions.

<b>AVERAGE</b>	<b>19.45%</b>	<b>19.27%</b>	<b>19.18%</b>

Table 11 presents the effect of three different calculation techniques for the  $\sigma$  parameters used in the radial basis functions of RBF model. Based on the mean errors, the distance-average method yields the lowest overall error at 5.81. Very close is the fixed value  $\sigma_1$  with a mean error of 5.87, while the maximum-distance method shows a slightly higher mean error of 5.96. The difference among the three methods is small, indicating that all can deliver comparable performance at a general level, with a slight advantage for the distance-average approach. At the level of individual datasets, however, significant variations are observed. For example, in Mortgage the  $\sigma_{\max}$  method reduces the error dramatically from 0.23 with  $\sigma_1$  to 0.021, while  $\sigma_{\text{avg}}$  also provides a much better result with 0.041. In Treasury the improvement is again substantial, as the error decreases from 0.47 with  $\sigma_1$  to just 0.08 using  $\sigma_{\max}$ . In Stock the reduction is clear, from 1.44 to 1.23, while in Plastic both  $\sigma_{\text{avg}}$  and  $\sigma_{\max}$  yield lower errors than  $\sigma_1$ . On the other hand, in datasets such as Housing, the use of  $\sigma_{\max}$  worsens performance, increasing the error from 15.36 with  $\sigma_1$  to 19.45. Similarly, in Auto and Baseball the lowest errors are obtained with  $\sigma_1$ , whereas the alternative techniques result in slightly worse performance. Overall, the results show that the choice of calculation technique for  $\sigma$  can significantly affect performance in certain problems, while in others the difference is negligible. Although no method consistently outperforms the others across all datasets, the distance-average method appears slightly more reliable overall, while the maximum-distance method can in some cases produce very large improvements but in others lead to a degradation of performance.

**Table 11.** Experimental results on the regression datasets with the application of the proposed method and different calculation mechanisms for the  $\sigma$  used in the radial functions.

In Figure 9, the significance levels are presented for the comparisons of different computation techniques for the  $\sigma$  parameters in the radial basis functions of the proposed machine learning model, based on the classification datasets. The comparisons performed  $\sigma_1$  vs  $\sigma_{\text{avg}}$ ,  $\sigma_1$  vs  $\sigma_{\max}$ , and  $\sigma_{\text{avg}}$  vs  $\sigma_{\max}$  did not show any statistically significant differences, since in all cases  $p > 0.05$ . This indicates that the choice of computation

method for the  $\sigma$  parameters does not substantially affect the performance of the model on classification problems. Therefore, it can be concluded that the model maintains stable performance regardless of which of the three computation techniques is used.

**Figure 9.** Statistical comparison of the obtained results on the classification datasets, where the proposed method was applied with a series of computation techniques for the range of  $\sigma$  values in the radial functions.

In Figure 10, the significance levels are presented for the comparisons of different computation techniques for the  $\sigma$  parameters in the radial basis functions of the proposed machine learning model, based on the regression datasets. The comparisons examined  $\sigma_1$  vs  $\sigma_{avg}$ ,  $\sigma_1$  vs  $\sigma_{max}$ , and  $\sigma_{avg}$  vs  $\sigma_{max}$  did not show any statistically significant differences, since in all cases  $p > 0.05$ . This means that the choice of computation method for the  $\sigma$  parameters does not have a substantial impact on the performance of the model in regression problems. Therefore, it can be concluded that the model demonstrates stable and consistent behavior regardless of which initialization technique is applied.

**Figure 10.** Statistical comparison of the obtained results on the regression datasets, using the proposed method and a series of computation techniques for the range of  $\sigma$  values in the radial functions.

#### 3.4. Experiments with the number of generations $N_g$

An additional experiments was executed, where the number of generations was altered from  $N_g = 50$  to  $N_g = 400$  to determine the stability of the proposed method. Table 12 examines the effect of the number of generations ( $N_g$ ) on the performance of the proposed classification model. The overall trend is downward: the mean error decreases from 20.56% at 50 generations to 19.46% at 100, essentially stabilizes at 200 with 19.45%, and improves slightly further at 400 to 19.11%. Thus, the largest gain arrives early, from 50 to 100 generations (about 1.1 points), after which returns diminish, with small but tangible additional gains. At the dataset level the behavior varies. There are cases with clear improvements as  $N_g$  increases, such as Alcohol (34.11%→27.02%), Australian (25.23%→21.39%), Ionosphere (13.94%→11.17%), Spiral (16.66%→12.45%), and Z\_O\_N\_F\_S (45.14%→38.26%), where more generations yield substantial benefits. In other problems the best value occurs around 100–200 generations and then plateaus or slightly worsens, as in Wdbc (best 4.84% at 100), Student (4.85% at 100), Lymography (21.64% at 100), ZOO (8.70% at 100), ZONF\_S (1.98% at 200), and Z\_F\_S (3.73% at 200). A few datasets show mild degradation with higher  $N_g$ , such as Wine (7.59%→10.24%), Parkinsons (17.32%→17.63%), and to a lesser extent Saheart, indicating that beyond a point further search is not beneficial for all problems. Overall, 100 generations deliver the major error reduction and represent an efficient “sweet spot,” while 200–400 generations extract modest additional gains and, in some datasets, meaningful improvements, at the cost of more computation and occasional local regressions.

**Table 12.** Experimental results on the classification datasets where the proposed method was applied and the the number of generations  $N_g$  was altered from  $N_g = 50$  to  $N_g = 400$ .

Table 13 examines the effect of the number of generations ( $N_g$ ) on the performance of the proposed regression model. At the level of average error, the best value appears at 100 generations with 5.61, marginally better than 50 generations at 5.65, while at 200 and 400 generations the mean error increases slightly to 5.87 and 5.86, respectively. This suggests that most of the benefit is achieved early and that further increasing the number of generations does not yield systematic improvement and may even introduce a small deterioration in overall performance.

Across individual datasets the picture is heterogeneous. Clear improvements with more generations are observed in Abalone, where the error steadily drops to 5.88 at 400 generations, in Friedman, with a continuous decline to 5.66, in Stock, improving to 1.33, and in Treasury, where performance stabilizes at 0.47 from 200 generations onward. In other problems the “sweet spot” is around 200 generations: for example, in Mortgage the error falls from 0.66 to 0.23 at 200 before rising again, in Housing it improves to 15.36 at 200 but worsens at 400, in BL the minimum 0.0004 occurs at 200, and in Concrete and HO there is a small but real improvement near 200. There are also cases where more generations seem to burden performance, such as Baseball and BK, where the error rises as  $N_g$  increases.

In several datasets the number of generations has little practical effect, with near-constant values in Airfoil, Quake, SN, and PL and only minor fluctuations in Dee, FA, Laser, and FY.

Overall, 100 generations provide an efficient and safe choice with the lowest mean error, while 200 generations can deliver the best results on specific datasets at the risk of small regressions elsewhere. Further increasing to 400 generations does not offer a general gain and may lead to slight degradation in some problems, pointing to diminishing returns and possible overfitting or instability depending on the dataset.

**Table 13.** Experimental results on the regression datasets where the proposed method was applied and the critical parameter  $N_g$ , that denotes the number of generations, was altered from  $N_g = 50$  to  $N_g = 400$ .

Laser	0.017	<b>0.015</b>	0.016	0.015
Mortgage	0.66	0.66	<b>0.23</b>	0.48
PL	<b>0.023</b>	0.023	0.023	0.023
Plastic	2.28	2.29	<b>2.28</b>	2.28
PY	0.02	0.023	0.021	<b>0.02</b>
Quake	<b>0.036</b>	0.036	0.036	0.036
SN	<b>0.026</b>	0.026	0.026	0.026
Stock	1.70	1.57	1.44	<b>1.33</b>
Treasury	0.65	0.61	<b>0.47</b>	0.47
AVERAGE	<b>5.65</b>	<b>5.61</b>	<b>5.87</b>	<b>5.86</b>

Figure 11 shows that increasing the number of generations from  $N_g = 50$  to  $N_g = 100$  yields a statistically significant improvement ( $p < 0.01$ , \*\*), indicating a meaningful reduction in error in this range. By contrast, the comparisons  $N_g = 100$  vs  $N_g = 200$  and  $N_g = 200$  vs  $N_g = 400$  are not statistically significant ( $p > 0.05$ , ns), which means that further increasing generations beyond 100 does not produce a consistent additional gain in performance. Overall, the results suggest that the main benefit is achieved early up to about 100 generations after which returns diminish and the differences are not statistically meaningful.

**Figure 11.** Statistical comparison for the executed experiments on the classification datasets using the proposed method and a series of values for the number of generations  $N_g$ .

In Figure 12, the p-value analysis on the regression datasets shows that the comparison between  $N_g = 50$  and  $N_g = 100$  is not statistically significant ( $p > 0.05$ , ns), so increasing generations in this range does not yield a consistent improvement. By contrast, moving from  $N_g = 100$  to  $N_g = 200$  is statistically significant ( $p < 0.05$ , \*), indicating a measurable reduction in error around 200 generations. Finally, the comparison between  $N_g = 200$  and  $N_g = 400$  is not statistically significant ( $p > 0.05$ , ns), suggesting diminishing returns beyond 200 generations. Overall, the findings indicate that for regression problems the benefit concentrates around 200 generations, while further increases in  $N_g$  do not guarantee additional consistent gains.

**Figure 12.** Statistical comparison for the executed experiments on the regression datasets using the proposed method and a series of values for the number of generations  $N_g$ .

### 3.5. Experiments with real - world problems

One practical problem that can be considered here is the prediction of the duration of forest fires that was presented recently for the Greek territory[112]. Using data from the Greek Fire Service, an experiment was conducted for the prediction of the duration of forest fires for the years 2014-2024. In this experiment, the following methods were used:

1. A neural network with 10 computing nodes, trained with the BFGS optimizer.
2. A Radial Basis Function with 10 weights, trained with the original method for RBF training.
3. The proposed method.

The results for the prediction of the duration are graphically illustrated in Figure 13. As is evident from the graph, in almost all years the classification error of the proposed technique is lower than the other two machine learning techniques.

**Figure 13.** Average classification error for the years 2014-2023 for the forest fires in the Greek territory.

The second real - world example is the PIRvision dataset [113], which includes occupancy detection data and it has 15302 patterns. The dimension of each pattern is 59. The same machine learning models were also used in the case and the average classification error for these methods is depicted graphically in Figure 14. One more time, the proposed method has lower classification error than the other methods involved in this experiment.

**Figure 14.** The experimental results for the PIRvision dataset.

#### 4. Conclusions

The final experimental evidence shows that the three-phase RBF training pipeline bound construction via K-means, global search with a GA inside those bounds, and local refinement with BFGS yields robust gains across heterogeneous classification and regression tasks. On classification, it achieves the lowest mean error (19.45%) with extremely significant superiority over all baselines ( $p < 0.0001$ ), on regression, it attains the smallest mean absolute error (5.87), with  $p < 0.01$  against BFGS/ADAM and  $p < 0.0001$  against NEAT/RBF-KMEANS/GENRBF. These results indicate that coupling broad exploration with constrained, precise local tuning mitigates numerical instability and local minima, providing reproducible performance improvements.

Sensitivity analyses reveal that the scale factor  $F$  materially affects classification at small-to-intermediate settings ( $F = 1 \rightarrow 2$  and  $F = 2 \rightarrow 4$  are significant at  $p < 0.01$ ), with no meaningful gain from  $F = 4$  to  $F = 8$ , whereas for regression the  $F$  comparisons are not significant, highlighting methodological stability. Alternative  $\sigma$  computation methods ( $\sigma_1, \sigma_{\text{avg}}, \sigma_{\text{max}}$ ) differ only marginally on average and show no significant differences in either task, reinforcing the method's resilience to low-level design choices.

Automating architecture and hyperparameter adaptation is a natural next step. Joint optimization of the number of RBF units,  $F$ , and bounds via Bayesian optimization or meta-learning could reduce manual tuning and improve generalization. Exploring alternative global optimizers (e.g., DE, PSO, CMA-ES) or hybrid GA and Bayesian strategies may accelerate convergence and enhance exploration, while in the final stage L-BFGS, bound-aware variants, and stochastic formulations could benefit large-scale, high-dimensional settings. A thorough ablation study to quantify each phase's contribution, along with broader post-hoc statistics, would strengthen the evidence base. From a systems perspective, parallel/distributed GA evaluations and GPU-accelerated RBF computations can materially cut runtime. Finally, extending benchmarks to strong non-RBF baselines and integrating the approach into AutoML pipelines together with analyses of interpretability and predictive uncertainty will provide a more complete picture of the method's limits and potential.

However, it should be emphasized that, despite its efficiency, the proposed method requires significantly more computational time than other machine learning techniques due to the serial application of the three training stages. In particular, the second stage of the genetic algorithm application requires significant computational time for its execution. However this time can be significantly reduced by using modern parallel computing techniques like OpenMP [114] or MPI [115].

**Author Contributions:** V.C. and I.G.T. conducted the experiments, employing several datasets and provided the comparative experiments. D.T. and V.C. performed the statistical analysis and prepared the manuscript. All authors have read and agreed to the published version of the manuscript.

**Funding:** This research received no external funding.

**Institutional Review Board Statement:** Not applicable.

**Informed Consent Statement:** Not applicable.

**Acknowledgments:** This research has been financed by the European Union : Next Generation EU through the Program Greece 2.0 National Recovery and Resilience Plan , under the call RESEARCH – CREATE – INNOVATE, project name “iCREW: Intelligent small craft simulator for advanced crew training using Virtual Reality techniques” (project code:TAEDK-06195).
